

## Detailed Explanation of Project & Components + Installation

The application runs a Java Servlet, which saves the user's search history and displays it when requested by the user. The servlet accesses a locally hosted MySQL database, which stores this information. In order to run this application and servlet on your machine, you will need to:

1. Set up a MySQL database on your machine
2. Create the necessary tables
3. Load the Servlet and have it running on a Tomcat server using Eclipse
4. Use an emulator to run the Android application on your locally hosted machine

In the Documentation folder, you will find a **Requirement Specification** folder, which contains all the necessary software. Once you have downloaded these items, follow the instructions for each of the steps above. The documentation is also provided in the same folder.
